## ON THE NINE-POINTS CIRCLE.

## By Professor Cayley.

If from the angles $A, B, C$ of a triangle we draw tangents to a conic $\Omega$, meeting the opposite sides in the points $\alpha, \alpha^{\prime}$; $\beta, \beta^{\prime} ; \gamma, \gamma^{\prime}$ respectively, then it is known that these six points lie in a conic. In particular, if the conic $\Omega$ reduce itself to a point pair $O O^{\prime}$, then we have the theorem, that if from the angles $A, B, C$, we draw to the point $O$ lines meeting the opposite sides in the points $\alpha, \beta, \gamma$ respectively; and to the point $O^{\prime}$ lines meeting the opposite sides in the points $\alpha^{\prime}, \beta^{\prime}, \gamma^{\prime}$ respectively, then the six points $\alpha, \alpha^{\prime} ; \beta, \beta^{\prime} ; \gamma, \gamma^{\prime}$ lie in a conic. We may inquire the conditions under which this conic becomes a circle. It may be remarked that one of the points say $O^{\prime}$ remains arbitrary: for if through the points $\alpha^{\prime}, \beta^{\prime}, \gamma^{\prime}$, we draw a conic (or in particular a circle) meeting the three sides respectively in the remaining points $\alpha, \beta, \gamma$, then (by a converse of the general theorem) the lines $A \alpha, B \beta, C \gamma$ will meet in a point $O$.

Using trilinear coordinates $(x, y, z)$ and writing $x: y: z=$ $a: b: c$ for the point $O$, and $x: y: z=a^{\prime}: b^{\prime}: c^{\prime}$ for the point $O^{\prime}$, it is at once seen that the equation of the conic through the six points is
$a a^{\prime} x^{2}+b b^{\prime} y^{2}+c c^{\prime} z^{2}-\left(b c^{\prime}+b^{\prime} c\right) y z-\left(c a^{\prime}+c^{\prime} a\right) z x-\left(a b^{\prime}+a^{\prime} b\right) x y=0$;
in fact, writing herein successively $x=0, y=0, z=0$, we see that the equation is satisfied by $x=0,(b y-c z)\left(b^{\prime} y-c^{\prime} z\right)=0$; by $\left.y=0,(c z-a x) c^{\prime} z-a^{\prime} x\right)=0$; and by $z=0,(a x-b y)\left(a^{\prime} x-b^{\prime} y\right)=0$ respectively. And it is to be observed that the equation may also be written

$$
\begin{aligned}
\left(a a^{\prime} x+b b^{\prime} y+c c^{\prime} z\right) & (x+y+z)-(b+c)\left(b^{\prime}+c^{\prime}\right) y z \\
& -(c+a)\left(c^{\prime}+a^{\prime}\right) x x-(a+b)\left(a^{\prime}+b^{\prime}\right) x y=0 .
\end{aligned}
$$

Suppose now that $x, y, z$ represent areal coordinates, viz. that ( $x, y, z$ ) are proportional to the perpendicular distances of the point from the sides, each divided by the perpendicular distance of the opposite angle from the same side; or, what is the same thing, coordinates such that the equation of the line infinity is $x+y+=0$. Then if $A, B, C$ denote the angles of the triangle, the general equation of a circle is
$\left(y z \sin ^{2} A+z x \sin ^{2} B+x y \sin ^{2} C\right)+(\lambda x+\mu y+\nu z)(x+y+z)=0$, where $\lambda, \mu, \nu$ are arbitrary coefficients.

Heuce, putting this

$$
\begin{aligned}
= & \Theta\left\{-(b+c)\left(b^{\prime}+c^{\prime}\right) y z-(c+a)\left(c^{\prime}+a^{\prime}\right) z x\right) \\
& \left.\quad-(a+b)\left(a^{\prime}+b^{\prime}\right) x y+\left(a a^{\prime} x+b b^{\prime} y+c c^{\prime} z\right)(x+y+z)\right\},
\end{aligned}
$$

we must have

$$
\begin{aligned}
& \Theta(b+c)\left(b^{\prime}+c^{\prime}\right)=-\sin ^{2} A, \\
& \Theta(c+a)\left(c^{\prime}+a^{\prime}\right)=-\sin ^{2} B, \\
& \Theta(a+b)\left(a^{\prime}+b^{\prime}\right)=-\sin ^{2} C,
\end{aligned}
$$

and then $\quad \Theta a a^{\prime}=\lambda, \Theta b b^{\prime}=\mu, \Theta c c^{\prime}=\nu$,
which last equations determine the values of $\lambda, \mu, \nu$,
Taking $a^{\prime}, b^{\prime}, c^{\prime}$ at pleasure, we have

$$
\begin{aligned}
& 2 a=\frac{1}{\theta}\left(\frac{\sin ^{3} A}{b^{\prime}+c^{\prime}}-\frac{\sin ^{2} B}{c^{\prime}+a^{\prime}}-\frac{\sin ^{3} C}{a^{\prime}+b^{\prime}}\right), \\
& 2 b=\frac{1}{\Theta}\left(-\frac{\sin ^{2} A}{b^{\prime}+c^{\prime}}+\frac{\sin ^{2} B}{c^{\prime}+a^{\prime}}-\frac{\sin ^{2} C}{a^{\prime}+b^{\prime}}\right), \\
& 2 c=\frac{1}{\theta}\left(-\frac{\sin ^{2} A}{b^{\prime}+c^{\prime}}-\frac{\sin ^{2} B}{c^{\prime}+a^{\prime}}+\frac{\sin ^{2} C}{a^{\prime}+b^{\prime}}\right),
\end{aligned}
$$

viz. $a, b, c$ having these values, the conic through the six points $\alpha, \beta, \gamma, \alpha^{\prime}, \beta^{\prime}, \gamma^{\prime}$ is the circle having for its equation $y z \sin ^{2} A+z x \sin ^{2} B+x y \sin ^{2} C$

$$
+\Theta\left(a a^{\prime} x+b b^{\prime} y+c c^{\prime} z\right)(x+y+z)=0
$$

and we may obviously without loss of generality give to $\theta$ any specific value, say $\theta=1$.

If $a^{\prime}=b^{\prime}=c^{\prime},=1$, then we have

$$
\begin{aligned}
& -4 a=\frac{1}{\theta}\left(-\sin ^{2} A+\sin ^{2} B+\sin ^{2} C\right) \\
& -4 b=\frac{1}{\theta}\left(\sin ^{2} A-\sin ^{2} B+\sin ^{2} C\right) \\
& -4 c=\frac{1}{\theta}\left(\sin ^{2} A+\sin ^{2} B-\sin ^{2} C\right)
\end{aligned}
$$

or writing for the convenience $\theta=-\frac{1}{2}$, the values of $a, b, c$
are $\frac{1}{2}\left(-\sin ^{3} A+\sin ^{2} B+\sin ^{3} C\right), \frac{1}{2}\left(\sin ^{3} A-\sin ^{2} B+\sin ^{2} C\right)$, $\frac{1}{2}\left(\sin ^{2} A+\sin ^{2} B-\sin ^{2} C\right)$ respectively. But we have

$$
A+B+C=\pi
$$

and thence

$$
\begin{aligned}
& \sin ^{2} A+\sin ^{2} B-\sin ^{2} C \\
= & \sin ^{2} A+\sin ^{2} B-\sin ^{2}(A+B) \\
= & 2 \sin A \sin B(\sin A \sin B-\cos A \cos B) \\
= & -2 \sin A \sin B \cos (A+B) \\
= & 2 \sin A \sin B \cos C
\end{aligned}
$$

and we thus have
$a, b, c=\sin B \sin C \cos A, \sin C \sin A \cos B, \sin A \sin B \cos C$, (or, what is the same thing, $a: b: c=\cot A: \cot B: \cot C$ ), and the equation of the circle is
$y z \sin ^{2} A+z x \sin ^{2} B+x y \sin ^{2} C$
$-\frac{1}{2}(x \sin B \sin C \cos A+y \sin C \sin A \cos B+z \sin A \sin B \cos C)$

$$
\times(x+y+z)=0 .
$$

We thus have $x: y: z=1: 1: 1$ for the point $O^{\prime}$, and $x: y: z=\cot A: \cot B: \cot C$ for the point $O ;$ viz $O^{\prime}$ is the point of intersection of the lines from the angles to the midpoints of the opposite sides respectively; and $O$ is the point of intersection of the perpendiculars from the angles on the opposite sides respectively: and the foregoing equation is consequently that of the Nine-points Circle.

## ON THE NINE-POINTS CIRCLE OF A PLANE TRLANGLE.

## By Professor Cayley.

I consider the circle which meets the sides of a triangle $A B C$ in the points $F, L ; G, M F ; H, N$ respectively, where ultimately $F, G, H$ are the feet of the perpendiculars let fall from the angles on the opposite sides, and $L, M, N$ are the mid-points of the sides: but in the first instance they are
