## 953.

## ON THE NINE-POINTS CIRCLE.

[From the Messenger of Mathematics, vol. xxini. (1894), pp. 23-25.]

If from the angles $A, B, C$ of a triangle we draw tangents to a conic $\Omega$, meeting the opposite sides in the points $\alpha, \alpha^{\prime} ; \beta, \beta^{\prime} ; \gamma, \gamma^{\prime}$ respectively, then it is known that these six points lie in a conic. In particular, if the conic $\Omega$ reduce itself to a point-pair $O O^{\prime}$, then we have the theorem that, if from the angles $A, B, C$, we draw to the point $O$ lines meeting the opposite sides in the points $\alpha, \beta, \gamma$ respectively; and to the point $O^{\prime}$ lines meeting the opposite sides in the points $\alpha^{\prime}, \beta^{\prime}, \gamma^{\prime}$ respectively, then the six points $\alpha, \alpha^{\prime} ; \beta, \beta^{\prime} ; \gamma, \gamma^{\prime}$ lie in a conic. We may enquire the conditions under which this conic becomes a circle. It may be remarked that one of the points say $O^{\prime}$ remains arbitrary: for if through the points $\alpha^{\prime}, \beta^{\prime}, \gamma^{\prime}$, we draw a conic (or in particular a circle) meeting the three sides respectively in the remaining points $\alpha, \beta, \gamma$, then (by a converse of the general theorem) the lines $A \alpha, B \beta, C \gamma$ will meet in a point $O$.

Using trilinear coordinates $(x, y, z)$ and writing $x: y: z=a: b: c$ for the point $O$, and $x: y: z=a^{\prime}: b^{\prime}: c^{\prime}$ for the point $O^{\prime}$, it is at once seen that the equation of the conic through the six points is

$$
a a^{\prime} x^{2}+b b^{\prime} y^{2}+c c^{\prime} z^{2}-\left(b c^{\prime}+b^{\prime} c\right) y z-\left(c a^{\prime}+c^{\prime} a\right) z x-\left(a b^{\prime}+a^{\prime} b\right) x y=0 ;
$$

in fact, writing herein successively $x=0, y=0, z=0$, we see that the equation is satisfied by $x=0, \quad(b y-c z)\left(b^{\prime} y-c^{\prime} z\right)=0$; by $y=0, \quad(c z-a x)\left(c^{\prime} z-a^{\prime} x\right)=0$; and by $z=0,(a x-b y)\left(a^{\prime} x-b^{\prime} y\right)=0$ respectively. And it is to be observed that the equation may also be written

$$
\left(a a^{\prime} x+b b^{\prime} y+c c^{\prime} z\right)(x+y+z)-(b+c)\left(b^{\prime}+c^{\prime}\right) y z-(c+a)\left(c^{\prime}+a^{\prime}\right) z x-(a+b)\left(a^{\prime}+b^{\prime}\right) x y=0
$$

Suppose now that $x, y, z$ represent areal coordinates, viz. that $(x, y, z)$ are proportional to the perpendicular distances of the point from the sides, each divided by the
perpendicular distance of the opposite angle from the same side; or, what is the same thing, coordinates such that the equation of the line infinity is $x+y+z=0$. Then if $A, B, C$ denote the angles of the triangle, the general equation of a circle is

$$
\left(y z \sin ^{2} A+z x \sin ^{2} B+x y \sin ^{2} C\right)+(\lambda x+\mu y+\nu z)(x+y+z)=0,
$$

where $\lambda, \mu, \nu$ are arbitrary coefficients.
Hence, putting this

$$
\begin{aligned}
=\Theta\left\{-(b+c)\left(b^{\prime}+c^{\prime}\right) y z-\right. & (c+a)\left(c^{\prime}+a^{\prime}\right) z x \\
& \left.-(a+b)\left(a^{\prime}+b^{\prime}\right) x y+\left(a a^{\prime} x+b b^{\prime} y+c c^{\prime} z\right)(x+y+z)\right\}
\end{aligned}
$$

we must have

$$
\Theta(b+c)\left(b^{\prime}+c^{\prime}\right)=-\sin ^{2} A
$$

$$
\Theta(c+a)\left(c^{\prime}+a^{\prime}\right)=-\sin ^{2} B
$$

$$
\Theta(a+b)\left(a^{\prime}+b^{\prime}\right)=-\sin ^{2} C
$$

and then

$$
\Theta a a^{\prime}=\lambda, \quad \Theta b b^{\prime}=\mu, \quad \Theta c c^{\prime}=\nu
$$

which last equations determine the values of $\lambda, \mu, \nu$.
Taking $a^{\prime}, b^{\prime}, c^{\prime}$ at pleasure, we have
viz. $a, b, c$ having these values, the conic through the six points $\alpha, \beta, \gamma, \alpha^{\prime}, \beta^{\prime}, \gamma^{\prime}$ is the circle having for its equation

$$
y z \sin ^{2} A+z x \sin ^{2} B+x y \sin ^{2} C+\Theta\left(a a^{\prime} x+b b^{\prime} y+c c^{\prime} z\right)(x+y+z)=0
$$

and we may obviously without loss of generality give to $\Theta$ any specific value, say $\Theta=1$.
If $a^{\prime}=b^{\prime}=c^{\prime},=1$, then we have

$$
\begin{aligned}
& -4 a=\frac{1}{\Theta}\left(-\sin ^{2} A+\sin ^{2} B+\sin ^{2} C\right) \\
& -4 b=\frac{1}{\Theta}\left(\sin ^{2} A-\sin ^{2} B+\sin ^{2} C\right) \\
& -4 c=\frac{1}{\Theta}\left(\sin ^{2} A+\sin ^{2} B-\sin ^{2} C\right)
\end{aligned}
$$

or writing for convenience $\Theta=-\frac{1}{2}$, the values of $a, b, c$ are

$$
\frac{1}{2}\left(-\sin ^{2} A+\sin ^{2} B+\sin ^{2} C\right), \quad \frac{1}{2}\left(\sin ^{2} A-\sin ^{2} B+\sin ^{2} C\right), \quad \frac{1}{2}\left(\sin ^{2} A+\sin ^{2} B-\sin ^{2} C\right)
$$

respectively. But we have

$$
A+B+C=\pi
$$

$$
\begin{aligned}
& 2 a=\frac{1}{\Theta}\left(\frac{\sin ^{2} A}{b^{\prime}+c^{\prime}}-\frac{\sin ^{2} B}{c^{\prime}+a^{\prime}}-\frac{\sin ^{2} C}{a^{\prime}+b^{\prime}}\right), \\
& 2 b=\frac{1}{\Theta}\left(-\frac{\sin ^{2} A}{b^{\prime}+c^{\prime}}+\frac{\sin ^{2} B}{c^{\prime}+a^{\prime}}-\frac{\sin ^{2} C}{a^{\prime}+b^{\prime}}\right), \\
& 2 c=\frac{1}{\Theta}\left(-\frac{\sin ^{2} A}{b^{\prime}+c^{\prime}}-\frac{\sin ^{2} B}{c^{\prime}+a^{\prime}}+\frac{\sin ^{2} C}{a^{\prime}+b^{\prime}}\right),
\end{aligned}
$$

and thence

$$
\begin{aligned}
& \sin ^{2} A+\sin ^{2} B-\sin ^{2} C \\
= & \sin ^{2} A+\sin ^{2} B-\sin ^{2}(A+B) \\
= & 2 \sin A \sin B(\sin A \sin B-\cos A \cos B), \\
= & -2 \sin A \sin B \cos (A+B), \\
= & 2 \sin A \sin B \cos C,
\end{aligned}
$$

and we thus have

$$
a, b, c=\sin B \sin C \cos A, \sin C \sin A \cos B, \sin A \sin B \cos C,
$$

(or, what is the same thing, $a: b: c=\cot A: \cot B: \cot C$ ), and the equation of the circle is

$$
\begin{aligned}
& y z \sin ^{2} A+z x \sin ^{2} B+x y \sin ^{2} C \\
& \quad-\frac{1}{2}(x \sin B \sin C \cos A+y \sin C \sin A \cos B+z \sin A \sin B \cos C)(x+y+z)=0
\end{aligned}
$$

We thus have $x: y: z=1: 1: 1$ for the point $O^{\prime}$, and $x: y: z=\cot A: \cot B: \cot C$ for the point $O$; viz. $O^{\prime}$ is the point of intersection of the lines from the angles to the mid-points of the opposite sides respectively; and $O$ is the point of intersection of the perpendiculars from the angles on the opposite sides respectively: and the foregoing equation is consequently that of the Nine-points Circle.
