Manuscript submitted January 13, 1982

A b s t r a c t — The populations of *Salmo trutta m. fario* and *Cottus poecilopus* were investigated in four streams of the River Dunajec: Biała Woda, Czarna Woda, Kamionka, and Grajcarek. The settlement density of fish in the investigated streams was higher than in other streams of this river system. However, the growth rate was lower than the average in the basin, except for a few cases, while the length-weight relationship reached about 255 g in the trout and 90 g in *Cottus poecilopus* Heckel.

K e y w o r d s: stream ecology, influence of pastoral economy, the West Carpathians, *Salmo trutta m. fario*, *Cottus poecilopus*, growth, weight.

1. Introduction

Fish of the Grajcarek stream and its tributaries, the Biała Woda, and Czarna Woda, and of the Kamionka stream were investigated in the years 1976—1978. The investigation was included in a general analysis of ichthyofauna of the River Dunajec upper basin in the current environmental conditions. A description of the investigated area was given by K o w n a c k i (1982).

* The investigations were carried out within Project MR.II.3.

2. Results and discussion

The catches carried out with electric current showed that all the investigated streams were settled by fish species characteristic for the upper parts of mountain streams, i.e., the stream trout (*Salmo trutta m. fario* L.) and *Cottus poecilopus* Heckel.

As compared with similar streams of the River Dunajec basin, the

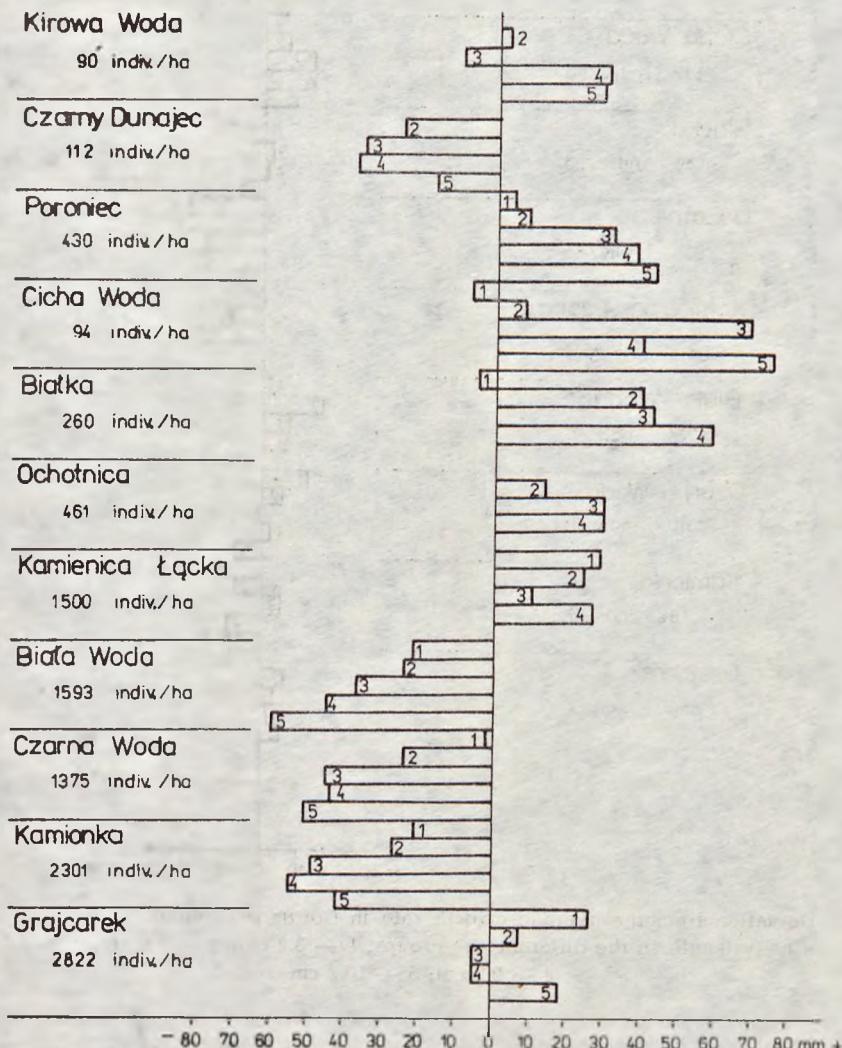

Fig. 1. Deviation from the average growth rate in *Salmo trutta m. fario*. 1—5 age-groups. Average for length in the different age groups: 1 — 6.4 cm; 2 — 12.8 cm; 3 — 18.2 cm; 4 — 22.3 cm; 5 — 25.6 cm

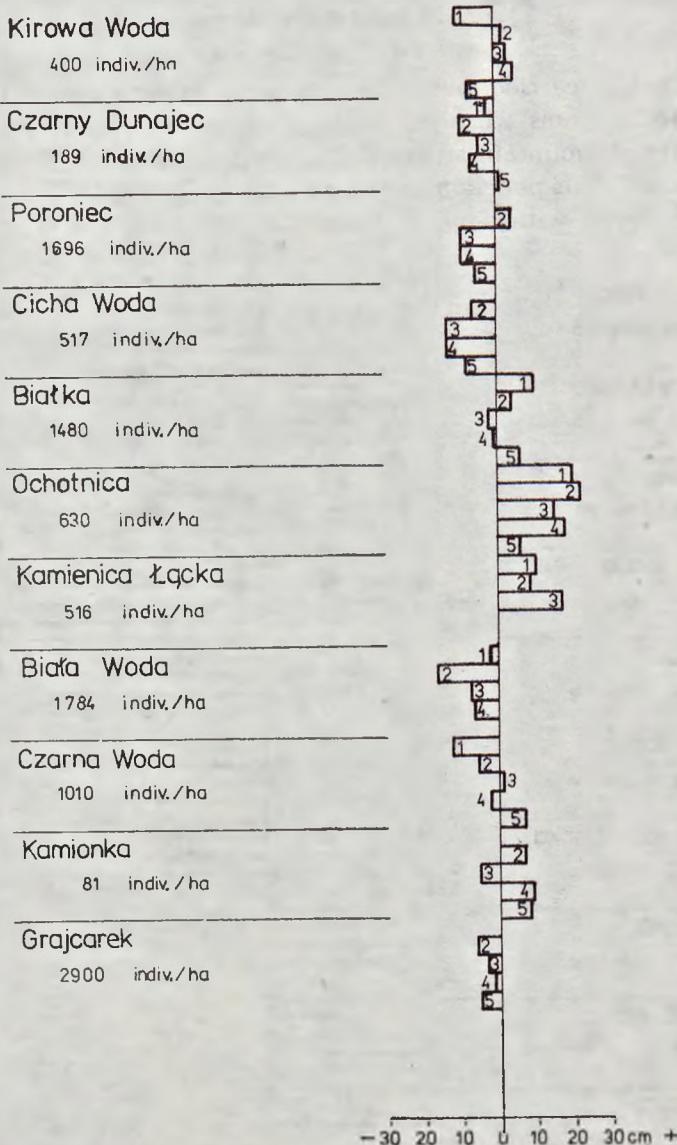

Fig. 2. Deviation from the average growth rate in *Cottus poecilopus*. 1—5 age-groups. Average body length in the different age-groups, 1 — 3.2 cm; 2 — 5.6 cm; 3 — 7.7 cm; 4 — 9.2 cm; 5 — 10.7 cm

numbers of representatives of the two species were high in the discussed streams (Starłmach 1982). They reached the following values per 1 ha of water surface (Table I): in the Biała Woda stream 1493 trout and 1784 *Cottus poecilopus* specimens, the corresponding numbers in the

Czarna Woda stream being 1375 and 1010, in the Kamionka 2301 and 81, and in the Grajcarek 2822 and 2900.

The age structure of the caught fish is given in Table I. The table shows that the following age groups of trout prevailed: in the Biała Woda 1-, 2-, and 3-years old fish, in the Czarna Woda 4- and 5-years old, in the Kamionka 1- and 2-years old, and in the Grajcarek 2- and 3-years old. Among the representatives *Cottus poecilopus* the prevailing age-groups were: in the Biała Woda 1- and 2-years old fish, in the Czarna Woda 2-years old, and in the Grajcarek 3- and 4-years old.

The growth of specimens of the trout and *Cottus poecilopus* species settling the investigated streams are shown in figs 1 and 2 and in Table II. They present the deviations from the average growth of the two species, calculated for fish in all streams with similar ichthyofauna in the Dunajec basin. The deviations from average growth, presented in the graphs, show that besides the fish from the River Czarny Dunajec at Kojsówka, the specimens of trout from the Biała Woda and Kamionka belong to the poorest growing fish in the Dunajec basin. The population from the Grajcarek stream is characterized by growth exceeding the average value. The increment of *Cottus poecilopus* is also poorer than the average calculated for the River Dunajec, except for 5-years old fish from the Czarna Woda and 2-, 4- and 5-years old from the Kamionka stream.

Increases in body weight (Table I) calculated in relation to body length are presented in graphs 3 and 4. As compared with other two-species streams of the basin, trout from the Czarna Woda, Kamionka, and Grajcarek stream are among the heaviest fish there. Contrary to the above-quoted populations, trout from the Biała Woda, with the same length, reach a weight of 240 g and are therefore classified in the group of medium body weight fish. The other investigated species, *Cottus poecilopus*, also shows a variable length-weight relationship in the different

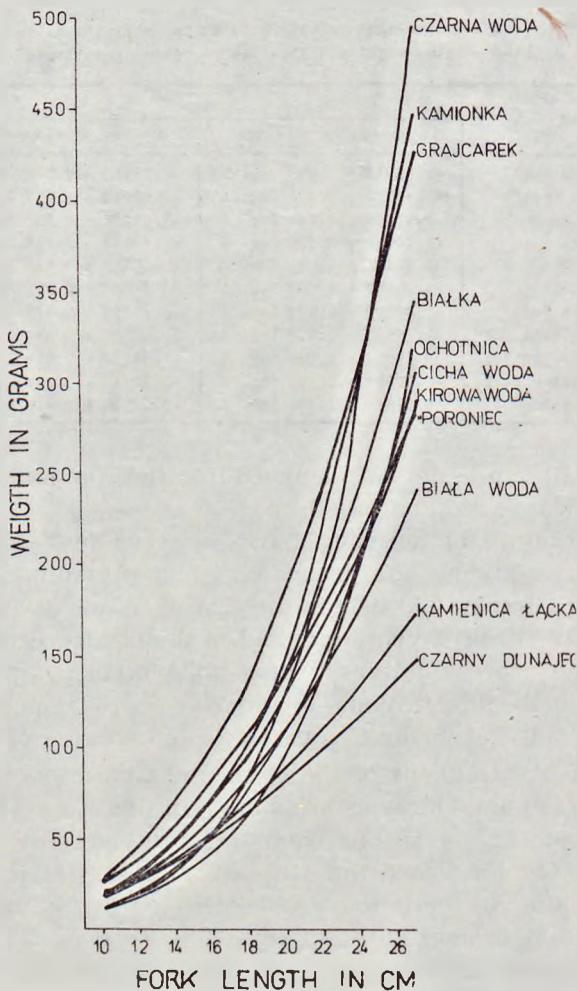

Fig. 3. Length-weight relationship *Salmo trutta m. fario*

streams. The representatives of this species from the Czarna Woda reach 125 g on the average at a length of 14 cm, and can be classified among the heaviest populations of *Cottus poecilopus* in the investigated basin, while the specimens from the Kamionka and Grajcerek reach 70—80 g, and those from the Biala Woda 34 g only. These results show that the variability range of *cottus gobio* body weight is fairly wide.

In recapitulating, trout from the streams of the Little Pieniny Mts (Małe Pieniny) have smaller body dimensions than the representatives of this species in other two-species streams of the River Dunajec basin. Contrary to body length the length-weight relationship in the investi-

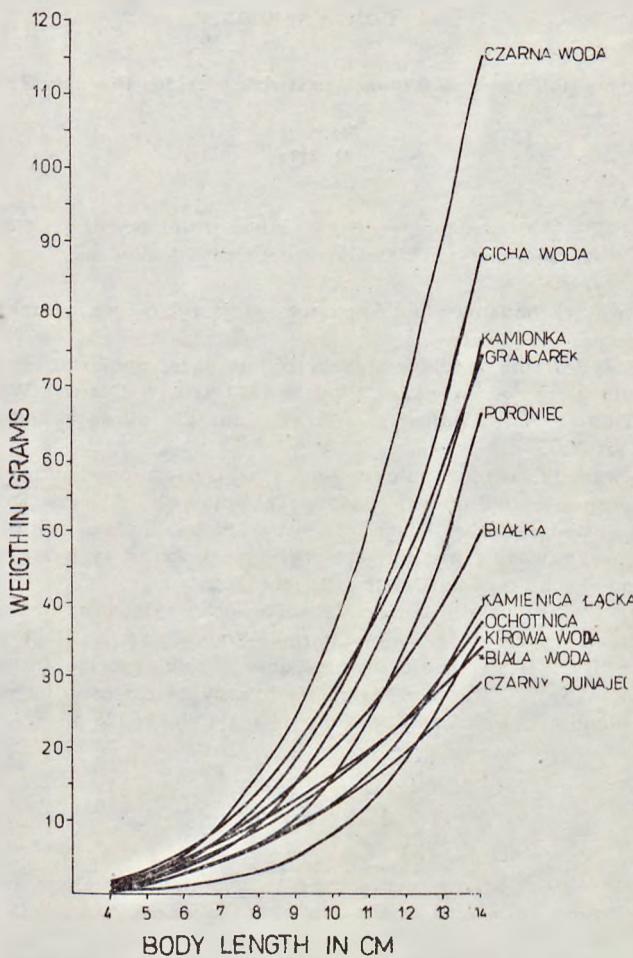

Fig. 4. Length-weight relationship *Cottus poecilopus*

gated fish was among the highest in the basin, except for the population of the Biała Woda stream.

The representatives of the other species living in the streams of the Little Pieniny Mts (Małe Pieniny), *Cottus poecilopus* Heckel, show a poorer growth rate than the populations in other streams of the basin, except for *Cottus poecilopus* from the Kamionka stream (fig. 2). Their length-weight relationship is also one of the highest in the streams of the River Dunajec upper basin.

3. Polish summary

Ekosystemy potokowe na terenach pastwisk górskich (Karpaty Zachodnie)

11. Ryby

W latach 1976—1978 zbadano populacje *Salmo trutta* m. *tario* i *Cottus poecilopus* w 4 potokach dorzecza Dunajca: Białej Wodzie, Czarnej Wodzie, Kamionce i Grajcarku. Badania te wykazały:

1. We wszystkich badanych potokach występują tylko dwa gatunki ryb — pstrąg potokowy i głowacz przepłetwy.

2. Gęstość zasiedlenia potoków (tabela I) jest duża, ponieważ w przeliczeniu na 1 ha wynosi dla pstrągów: w Białej Wodzie 1593 szt., w Czarnej Wodzie 1375 szt., w Kamionce 2301 szt. i w Grajcarku 2822 szt. oraz dla głowaczy odpowiednio 1784, 1010, 81 i 2900 sztuk.

3. Tempo wzrostu pstrąga potokowego, z wyjątkiem populacji żyjącej w Grajcarku, jest mniejsze niż w innych podobnych potokach dorzecza Dunajca (ryc. 1). Średni wzrost głowaczy natomiast (ryc. 2) jest w Białej Wodzie i Grajcarku mniejszy, w Czarnej Wodzie równy, a w Kamionce wyższy niż wzrost tych ryb w innych dwugatunkowych potokach dorzecza Dunajca (tabela II).

4. Stosunek ciężaru do długości ciała waha się u pstrągów przy długości 27 cm od 240 g w Białej Wodzie do 495 g w Czarnej Wodzie (ryc. 3). U głowaczy podobnie jak u pstrągów (ryc. 4) występuje również duża rozbieżność ciężaru ciała ryb z poszczególnych potoków. Głowacze z Białej Wody przy 14 cm długości mają 35 g wagę, gdy tej samej długości ryby z Czarnej Wody osiągają ciężar 125 g.
