GESAPU

Geoinformation technologies, spatio-temporal approaches, and full carbon account for improving accuracy of GHG inventories

Deliverable 1.3. Information technology for spatial greenhouse gas emission inventory ready to use for any part of Poland, and any time period

Rostyslav Bun, Olha Danylo (Editors),

Petro Topylko, Boychuk Kh., Nadiia Charkovska, Mariia Halushchak, Oleksandr Striamets
Lviv Polytechnic National University, Ukraine;

Zbigniew Nahorski, Joanna Horabik, Jolanta Jarnicka,

Systems Research Institute, Polish Academy of Sciences, Poland

Delivery Date: M38

Project Duration	24 June 2010 – 23 June 2014 (48 Months)
Coordinator	Systems Research Institute of the Polish Academy of Sciences (SRI)
Work package leader	Lviv Polytechnic National University, Ukraine Systems Research Institute of the Polish Academy of Sciences (SRI)

Project: #247645. Call: FP7-PEOPLE-2009-IRSES, Marie Curie Actions—International Research Staff Exchange Scheme (IRSES).

Work package 1. Spatially resolved greenhouse gas inventory for Poland

Deliverable 1.3. Information technology for spatial greenhouse gas emission inventory ready to use for any part of Poland, and any time period

Content

1. **Geoinformation technology for spatial GHG inventory: electricity and heat production**
2. **Geoinformation technology for spatial GHG inventory: residential sector**
3. **Geoinformation technology for spatial GHG inventory: transport sector**
4. **Geoinformation technology for spatial GHG inventory: industrial sector**
5. **Geoinformation technology for spatial GHG inventory: agriculture sector**
6. **Geoinformation technology for spatial GHG inventory: LULUCF sector**

4. Geoinformation technology for spatial GHG inventory: Industrial sector

According to the IPCC methodology industrial processes sector is one of the main considerable sectors for greenhouse gas emission reduction. The GHG emissions in this sector are caused by chemical or physical transformations of materials during manufacturing of industrial products. Major GHG emissions source categories are the cement production, lime production, iron and steel industry, ammonia production, nitric acid production, consumption of hydrofluorocarbons (HFC) in refrigerating and air conditioning equipment, etc. Emissions in this sector account for about 7% of the total net emissions (National Inventory Submissions). The data on production of industrial products in Poland is available only on country level.

Carrying out the spatial GHG inventory at the level of every elementary object in the industrial sector consists of three main steps (*Figure 4.1*):

- Import of statistical data;
- Disaggregation of statistical data on manufacturing of industrial products;
- Greenhouse gas emission estimation.

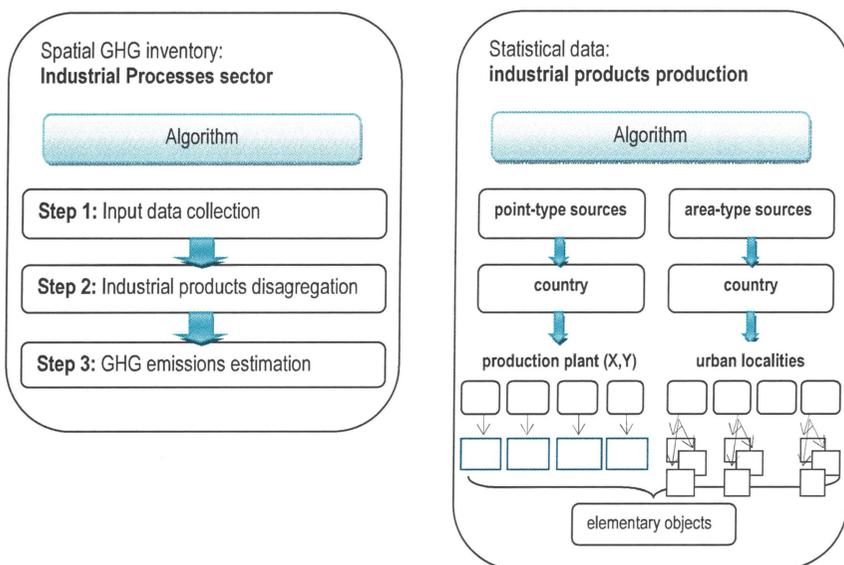

Figure 4.1. The algorithm of the spatial greenhouse gas emissions inventory in the industrial sector.

The information technology was created for realization of the developed methodology. The logical structure of the algorithm is presented in *Figure 4.2*. Each step of this methodology was implemented as a program module, using a geographic information system. Thus, the created information technology consists of three program modules: **Ind1** collection, **Ind2** disaggregation, and **Ind3** estimation:

(1) **Ind1 collection.** All input data are given as digital maps, Excel tables (with the statistical data from GUS and separately with the data from main production plants in each emissions source category) and emission factors. There are point-type and area-type sources of the GHG emissions in the industrial sector. For instance, meat and bread production plants are assumed as area-type sources, that is why the population density map is used to prepare the georeferenced database with the elementary objects. We consider the area within which the population density is the same as the elementary object. The population map was created using raster data on population density disaggregated according to the Corine land cover 2000 (Gallego, 2010). The map was updated with the data for 2010. The data concerning the population in urban localities also are updated for 2010.

In the **Ind1 collection** module the statistical data was imported from Excel tables. The data on production of main industrial products is available on country level. Information (location, production capacity, and geographic coordinates) about large production plants in each emissions source category was collected and saved as Excel tables, and then respective digital maps of production plants were built, using this information. The imported Excel tables contain the important statistical data which characterizes activities in the industrial sector and is essential for carrying out the greenhouse gas emission inventory. In particular, they contain:

- Characteristics of activity of industrial production plants in each source category with a link to the map of administrative units, for example, a cement production plant linked to municipality (*Table 4.1*);
- Greenhouse gas emission factors.

(2) **Ind2 disaggregation.** The statistical data on the amount of industrial products are disaggregated from country level to the level of plants, proportionally to production capacities of large production plants from digital maps, which are built in previous module. In the case of area-type emissions source, when a lot of small plants are localized at a small part of territory, the statistical data are disaggregated from the level of the country or voivodeships to the level of urban localities proportionally to the population density data.

(3) **Ind3 estimation.** Using specialized geoinformation system, the estimates of greenhouse gas emission have been obtained. Firstly, we estimate the GHG emissions from each category of emissions sources in subsectors of the industrial sector due to the IPCC classification: Mineral products (number of categories – 7), Chemistry (9), Iron and Steel industry (9), Other production

(1), consumption of Halocarbons and SF₆ (7). The values of emissions in this case depend on the disaggregated statistical data on production and respective specific emission factors, which characterize activity of individual enterprise and used production technologies. The emission factors vary by production plant. For instance, the results of modeling of the GHG emissions from nitric acid production plants are presented as table in *Figure4.3* and, additionally, illustrated in a built digital map for the category “Nitric acid production” of chemical industry in *Figure4.4*. In the result of overlaying the digital map of elementary objects and the digital map of nitric acid production plants, we transferred the values of GHG emissions estimated on the level of plants to elementary objects proportionally to the sum of productions from the plants that, are within these objects.

Using the developed information technology, we carried out numerical experiments from GHG emissions estimation for 2010 on the base of respective statistical information on industrial products production in this year. As the result, we obtained the estimates of the greenhouse gas emissions at the level of elementary objects for 2010 for all categories in the industrial sector. The georeferenced database contains information about carbon dioxide, methane, and nitrous oxide emissions from main categories of human activity due to the IPCC methodology, as well as the estimates of greenhouse gas emissions from indirect informations, for example, emissions of carbon monoxide, nitrous oxides, sulphur dioxide, non-methane volatile organic compounds from pulp-paper industry, and food industry. Total greenhouse gas emissions in CO₂-equivalent also are represented in georeferenced database with inventory results. Every elementary object from digital map is linked to the exact row of the georeferenced database, which contains information about greenhouse gas emissions in the industrial sector.

The georeferenced database contains the results of the spatial GHG emission inventory and consists of geographic elements and the table of attributes with activity data, disaggregated values on industrial products production, total GHG emissions, and emissions for each emissions source categories. Using the GIS-tools, the obtained results may be presented as thematic maps. The final georeferenced database is ready to use in further research.

As an example, we illustrated the results of the spatial GHG emissions inventory for elementary objects of one of the 16 regions (Silesian voivodeship - *Figure4.5*). The figure shows territorial distribution of CO₂ emissions from main industrial processes of cement, lime, glass, soda ash production and lime and dolomite use in one region. For displaying the results at elementary objects, the map of the municipalities of Silesian region was split in grids of defined size (2x2 km).

For correct operation of the software the following tools are needed:

- IBM-compatible PC;
- Windows Service Pack 2 / 2002/XP;
- MS Office (MS Excel 2003 +);
- GIS MapInfo 8,0 +;
- Module of IPCC methodologies for MS Excel.
