

KAZIMIERZ BROWICZ

Distribution of woody Rosaceae in W. Asia XI

Crataegus aronia (L.) Bosc. ex DC.

C. aronia (L.) Bosc ex DC. Prodr. 2 : 629 (1825)

Syn.: *C. azarolus* L. β *aronia* L., Spec. Pl. 477 (1753); *C. azarolus* (non L.) auct. plur. Fl. Or.; *C. chrysoclada* Gandgr. Fl. Cret.: 35 (1916); *C. azarolus* L. subsp. *aronia* (L.) H. Riedl, in K. H. Rechinger Fl. Iranica 66 : 56 (1969).

Arbor ad 8 m alta, spinosa, ramis hornotinis tenuibus, tomentosis, folia firma glauca, utrinque breviter pubescentia demum, praecipue subtus, fere glabra, folia superiora ramorum fertilium 2 - 3.5 (5) cm longa, 1.5 - 3.2 cm lata, profunde 3 - 5 lobata vel subpartitia, lobis obtusatis, mucronatis, nonnunquam breviter acutis, integerrimis vel apice 1 - 3 dentatis, raro inaequaliter inciso-dentatis (icon.: Pococke t. 85; exs.: Bornmüll., no. 1026). Inflorescentia tomentosa, 2 - 3.5 cm diam., compacta: flores 15 - 18 mm diam., sepala late triangularia acuta, styli 2 - 3, fructus globosi, vel ovato globosi, plerumque 12 - 13 (20) mm in diam., lutei, 2 - 3 pyreni; pyrenae dorso convexae, latae, pauc costatae, ventre planae vel carinatae, hypostyli triangulari (acc. to Pojarkova, 1939).

Crataegus aronia is one of the more characteristic hawthorns occurring in southwestern Asia. Although it is relatively easily distinguished from other closely related species from that region, the question of its name is still controvertial. Both in herbarium collections and in the floristic literature almost to about the same extent another name is used for it namely *C. azarolus* L. Some authors believe, that these are two, independent species, while others consider the names as synonyms, and usually they consider the name *C. azarolus* as being the older one and therefore give it priority. These controversies concern not only older literature but are also voiced in the most recent works. For example Meikle (1966) for Iraq, Franco (1968) for Europe and Mouterde (1970) for Syria and Lebanon use the name *C. azarolus*, while Riedl (1969) for Iran and Iraq uses the name *C. azarolus* subsp. *aronia* and Browicz (1972a) for Turkey calls it *C. aronia* (Fig. 1).

With all this is associated an absence of detailed information on its geographic distribution. According to Diapulis (1933) both *C. azarolus* and *C. aronia* occur in western Asia and on Crete, according to Franco

Phot. K. Jakusz

Fig. 1. A herbarium specimen of *Crataegus aronia* from Turkey (Royal Botanic Garden, Edinburgh)

(1968) *C. azarolus* grows in southern Europe, but only as a cultivated and domesticated plant and in the wild state as var. *aronia* in Crete.

The first and so far the only attempt at clarifying these complex questions of nomenclature in the taxa has been undertaken by Pojarkova (1939), however her work is little known which presumably has been caused by the fact that it has been published just before the war. Her line of thinking is as follows. Linnaeus in his "Species Plantarum" (1753), has recognized both *C. azarolus* and its variety β *Aronia*. After a general diagnosis "Crataegus foliis obtusis, bitrifidis, subdentatis" Linnaeus quotes for the type species the name taken from Bauhin

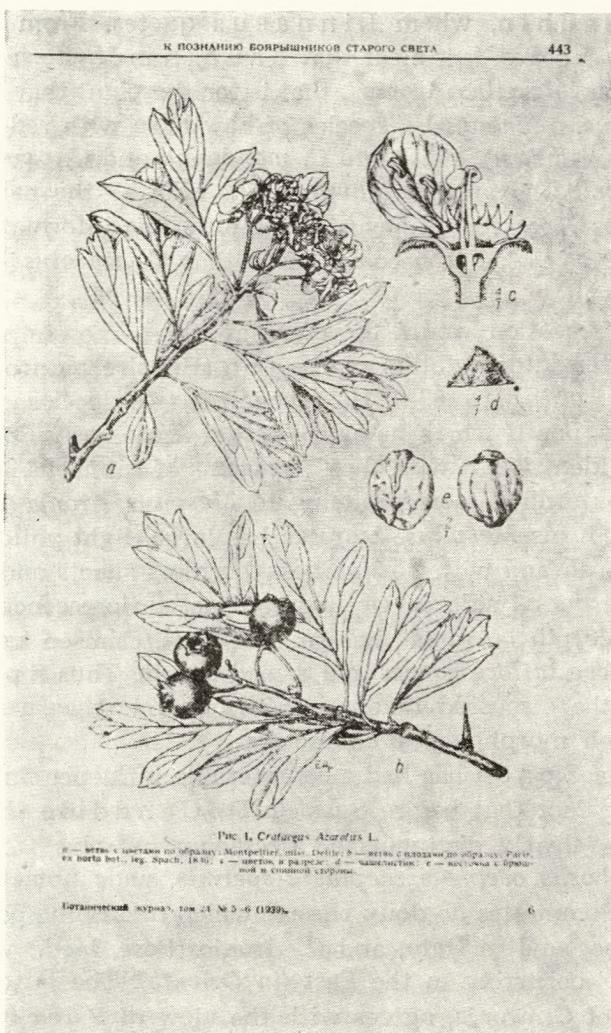

Fig. 2. The illustration of *Crataegus azarolus* L. (acc. to Pojarkova, Jour. Bot. USSR, 24, 5, 1939)

from his "Pinax theatri botanici, 453" and from "Historia plantarum, 1 : 67". In the first case Bauhin says: "Mespilus apii folio laciniato", and in the second: "Mespilus Aronia veterum". As regards the variety " β Aronia" Linnaeus has used the diagnosis of Pococke (Orient. 189, t. 85) "Mespilus orientalis apii folio, subtus hirsuto". At the same time Pojarkova points out that the diagnosis of Pococke is somewhat wider and contains the following expression "fructu magno luteo". This description of the colour of the fruit is of considerable significance for the further conclusions of Pojarkova.

Since the diagnosis of Linnaeus is very short Pojarkova has

looked into Bauhin, whom Linnaeus quotes. From the detailed description, on 5 pages, it is clear that Bauhin in "Historia plantarum", under the name "*Mespilus Aronia*", that is for the plant that Linnaeus calls *C. azarolus*, understood a species of hawthorn with red fruit (*fructu fert rotundum, rubrum*), similar to *C. monogyna* and *C. oxyacantha* (*Mespilus Aronia foliis ad spinum album; Spina alba* — the name given for the two species referred to above). Combining this information with the diagnosis of Pococke it becomes clear that *C. azarolus* has red fruit and β *Aronia* yellow ones.

The whole question would therefore appear to be simple if it were not for the later interpretation of Spach (Histoire naturelle des végétaux, Phanerogames, II, 1834). He recognizes two species of hawthorns with big fruits, one of which he calls "néflier azérolier — *Mespillus Azarolus* L." and identifies it with the *C. azarolus* of Linnaeus, and the other "néflier faux-azérolier" corresponding to *Mespilus Aronia* Willd. According to Spach his *Mespilus Azarolus* has large, light yellow fruit with a slight red flush and with 2 - 3 stones, thornless shoots and large leaves downy on the dorsal side as well as compact inflorescences on a short axis, while "*Mespilus Aronia*" has smaller fruit, crimson in colour, with two stones, loose inflorescences and armed shoots. Thus Spach has not only treated the discussed taxons inversly as Linnaeus, but he has also mixed their morphological characters.

The view of Spach has had a considerable influence on later studies in spite of the fact that before Spach De Candolle (*Prodromus* II: 629, 1825) has clearly distinguished *Crataegus azarolus* L., the fruit of which is "*globosus occineus saepius 2-spermis, unde nomen vulg. Monspessulanum Pommettes de doux closes*" which occurs in sparse woods of southern France and in Italy, and *C. Aronia* (Bosc, ined.) with "*Fructus dicitur flavus*" occurring in the East (*in Oriente*). The latter description of the origin of *C. aronia*, agrees with the view of Pococke, who has made an illustration of the species on the basis of a specimen raised in England from seeds collected in Palestine (Pojarkova, 1939).

All these inconsistencies could be best untangled by the herbarium type specimen (particularly if it had fruits) of *C. azarolus*, however, as Pojarkova reports it has not been retained until modern times and in the herbarium of Linnaeus it is substituted by another species of hawthorn originating from America with large wide leaves, with very shallow but sharp lobes and a sharply serrate leaf blade.

Basing on the conclusions presented above Pojarkova has prepared an extensive Latin diagnosis of *C. azarolus*, which I quote below:

C. azarolus L., Spec. Plant. 477 (1753). Syn.: *Mespilus azarolus* Poir. in Lam. Ecycl. méth. 4 : 438 (1797); *Mespilus Aronia* Spach, Hist. vég. 2 : 69 (1834); *Crataegus maroccana* Lindl., Bot Regist. 22 tabl. 1855 (1836); *Mespilus azarolus* var. *erythrocarpa* Moris, Fl. Sard. 2 : 44 (1840 - 1843);

Crataegus ruscinonensis Gren. et Blanc. in Billotia 1: 71 (1864 - 1866);
Crataegus azarolus var. *ruscinonensis* Fiori, Fl. d'Ital. 1: 785 (1923 - 1925).

Arbor ad 6 m alta, ramis inermibus vel spinosis, hornotinis tenuibus pubescentibus vel subtomentosis. Folia adulta glabra vel supra sparse adpresso pilosa, petiolis laminis 2.5 - 6-plo brevioribus, ambitu ovato-cuneata vel rhomboidea; ramulorum fertilium folia inferiora apice grosse dentata vel triloba, non raro elongata, caetera profunde triloba, lobis lanceolatis, ca. 2.5 - 1, mucronulatis, integris vel apice 1 - 3 dentes gerentibus, lobo medio non raro tripartito, incisuris fere in medio laminae dispositis. Inflorescentia composita, satis laxa, 8 - 12-flora, pedunculis, pedicellis, sepalisque pubescentibus; hypanthium subtomentosum, pedunculi 3 - 5 cm longi, sepala late triangularia, in fructu reflexa, acuta, styli plurimque 2 (1 - 3). Fructus subglobosi, ca. 12 (ad 15) mm in diam., lateritii vel rubri, 2 (1 vel 3) - pyreni (Fig. 2).

According to Pojarkova *C. azarolus* L. occurs only in southern France (without the eastern part — Maritime Alps) and in Italy. The reports from Spain and Algeria are probably doubtful. It is interesting that the herbarium collections of this species are rare and as a rule were made in the first half of the XIX century, while Pojarkova herself has only seen a few. Besides *C. azarolus* L. Pojarkova has described another European species of hawthorn with large fruit but with yellow ones, and she has called it *C. linnaeana* Pojark. It grows in Sicily, in southern and central Italy and possibly also in southern France, while in southern Spain and on Sardinia it is probably only in cultivation or gone wild. In "Flora Europaea" it has however been omitted by Franco (1968).

Considering the morphological characters of *C. azarolus* and *C. linnaeana* Pojarkova admits that there exists the possibility that *C. azarolus* is only a hybrid between the latter, a yellow fruited hawthorn and the red fruited *C. monogyna*, and she refers also to a similar view expressed in the previous century by Planchon (Le *Crataegus Aronia* (Spach.) dans ses rapports avec l'Aubépinex et l'Azerolier d'Italie, Comptes rendus Acad. Paris 74, 1872). Recently also Poletiko (1954) has expressed the view that it is such a hybrid. If this proved true, then it would be easy to understand such morphological characters as: variable number of stones (1 - 3), colour of the fruit, loose inflorescence structure of *C. azarolus*.

However still the position of the yellow fruited European *C. linnaeana* remains unclear — is it a wild species or is a cultivated form. According to Pojarkova it is characterized by large leaves (up to 7.5 cm long and 5.5 cm wide), and thick shoots without thorns. Pojarkova contrasts these characters with those of *C. aronia*, which has leaves 3.5 (5) cm long and up to 3.2 cm wide and the shoots are armed. It appears that the latter character is a relative one. While looking

through rich herbarium collections of *C. aronia*, from various parts of its range (as is usual for woody plants, they are not full, usually represented on a sheet by only one or two twigs) I came to the conclusion that in *C. aronia*, similarly as in several other species from the sub-family Maloideae (e.g. *Pyrus communis*), thorns are well visible in young specimens and in those growing wild, while old trees and the cultivated forms have none or almost none. It is not unlikely therefore that *C. linnaeana* represents only a selected cultivated form of *C. aronia*, introduced into cultivation centuries ago, possibly by the Arabs in IX-X century into Sicily (or even into Spain). This could be an explanation for the similarity of the Arabic name for the yellow fruited hawthorn used throughout south western Asia, "zarur" with the Italian name: "azzarolo, lazzarolo, azzaruolo" or else the French name "azarole, azérole or azérolier". Even today the yellow fruited form of hawthorn is cultivated for consumption purposes in places of Iraq (Meikle, 1966), Syria and Lebanon (Mouterde, 1947).

C. triloba Poir. from northwestern Africa (mountains of Tunesia, Algeria and Marocco) is also a thornless, yellow fruited hawthorn related to *C. aronia*. It differs from *C. linnaeana* in having much smaller leaves (up to 4.5 cm long and 3 cm wide) with a blade serrate only at the top or provided with very shallow lobes pointing upwards (*C. aronia* usually has deeply lobed leaves).

Contrasting the European *C. azarolus* of Linnaeus with the Asiatic *C. aronia*, Pojarkova has recognized within the section Azaroli Loud. a separate series of species, with she has called Ponticae Pojark. She has included in the series besides *C. aronia* the species mentioned above *C. linnaeana* and *C. triloba* as well as *C. pontica* C. Koch. This latter hawthorn occurs on a few stands in Turkey, in eastern Transcaucasia, in northern Iran, in the moutains of Kopet-Dagh in Turkmenia and in Middle Asia (Pamir-Alai, western Tien-Shan). This species also used to be considered as *C. azarolus* and similarly as *C. triloba* and *C. linnaeana* it is to be devoid of thorns.

Thus according to Pojarkova in the series Ponticae only *C. aronia* has thorny shoots. She claims that the range of the species covers Palestine (*locus classicus*), Syria, Cyprus, Rhodos, Crete, southern Turkey, southwestern Iran and northern Iraq. In spite of the limited number of herbarium specimens Pojarkova had access to, it is striking how good was her judgement concerning the geographic distribution of the species, though of course a detailed delimitation of the range was out of the question at the time.

Basing on the conclusions presented above and on the rich herbarium materials quoted below, as well as on the information from the literature (assuming that *C. azarolus* of southwestern Asia corresponds to *C. aronia*) I have prepared a point map of the distribution of *C. aronia* (Fig. 3).

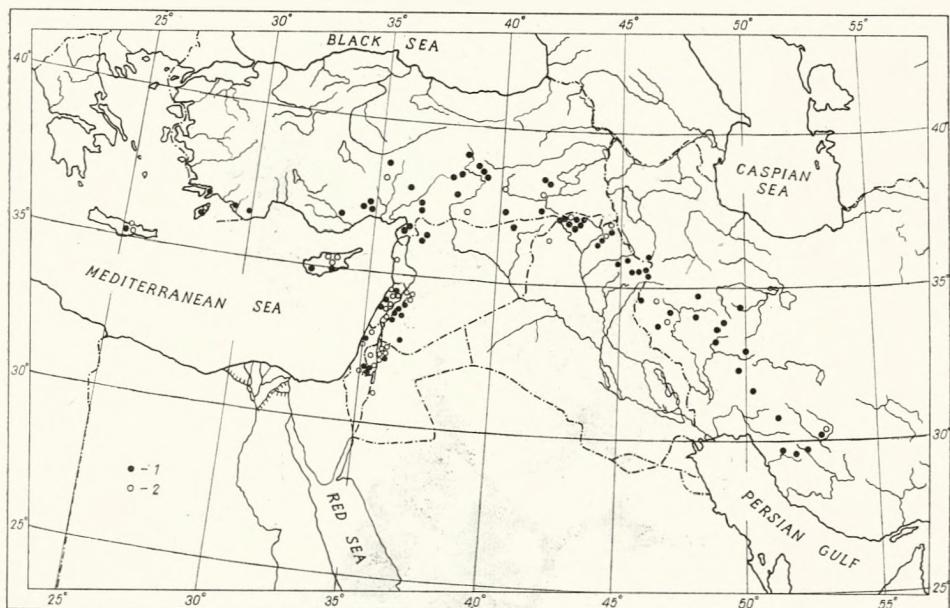

Fig. 3. The distribution of *Crataegus aronia*: 1. herbarium specimens, 2. literature

In some cases on the basis of the available knowledge about the range I was hesitant in accepting some of the literature quotations, and to be on the safe side I have not included these on the map. Thus I have not included the stand reported by Birand (1952) from Beykoz near Istanbul; neither from that place nor from anywhere in the vicinity has *C. aronia* been mentioned. I have also left out several stands reported in Paphlagonia, from the vicinity of Ankara (Krause, 1934; Czecczott, 1939; Bornmüller, 1940; Birand, 1952), since from that region I have not seen a single herbarium specimen that would confirm the observations. They do not have a link with the main part of the range of *C. aronia* and one can suspect that they belong to some completely different species, such as the original variety *C. orientalis* Pall var. *obtusata* Browicz (Browicz, 1972b). To this variety belongs the herbarium specimen of Sintenis (no. 4464) from Tossia, which has in fact been described by Bornmüller (1940) as *C. azarolus*.

Then basing on the opinion of Pojarkova about the range of *C. pontica* (a species related to *C. aronia*) I have also omitted the reported stands from northern Iran and from Turkmenia, assuming that they belong to *C. pontica*. It is possible that also some of the published reports of *C. aronia* from Jordania, Israel and Syria concern *C. sinaica* Boiss., a species very similar to *C. aronia* in leaf shape. However if such were the case the range of *C. aronia* would not be affected, since the herbarium collections I have seen sufficiently delimit it. The range, being very similar to that of *Pyrus syriaca* Boiss., indicates clearly that

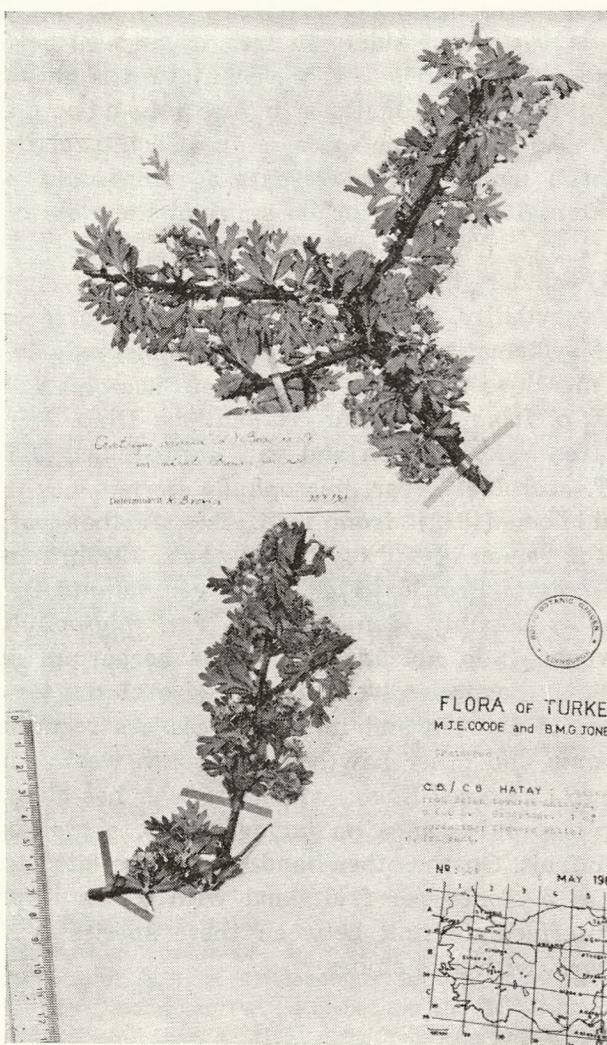

Phot. K. Jakusz

Fig. 4. *Crataegus aronia* var. *dentata* — type specimen (Royal Botanic Garden, Edinburgh)

C. aronia is an eastern-Mediterranean species, which on the one hand has a link with southern Europe and north-western Africa (*C. linnaeana* and *C. triloba*) and on the other with the Caucasus and Central Asia (*C. pontica*).

In its vertical distribution *C. aronia* is characterized by a considerable range of stands. The lowest stands are located even below 100 m elevation while the upper most ones reach 2000 m (Zagros Mts., M. et D. Zohary, *in sched* 1064), most commonly however this hawthorn occurs at medium mountain elevations between 600 and 1600 m. Only

Phot. K. Jakusz

Fig. 5. *Crataegus aronia* var. *minuta* — type specimen (Royal Botanic Garden, Edinburgh)

in Iran where *C. aronia* attains its highest elevations the majority of known stands have been found at elevations above 1200 - 1400 m. It grows primarily on a calcareous, rocky substratum, though it has also been found growing on sandstone and basalts. It is a common component of sparse woods and oak thickets, and thanks to its considerable potential for coppicing it will remain in many places even after complete destruction of these communities. Sometimes its participation in oak forests is considerable and as has been reported by Kasapligil (1956b) in Jordan in an oak forest in the mountains of Ajlun, 5 km east of Staenia

Forest Station, *Quercus infectoria* comprises 69%, *Q. coccifera* 30% and *Crataegus aronia* 1% of the stand. In Iraq it can also be found in pine forests (Meikle, 1966). It is very resistant to draught, and therefore it frequently enters regions of desert nature (Mouterde, 1947). Here and there it can be found near roads or in agricultural fields, where it has possibly been planted or represents a remnant of the destroyed natural vegetation. The reason for its survival there is to be sought in the edible fruit.

It is little wonder therefore that *C. aronia* is characterized by a considerable variability. Several varieties have been recognized within it, however the systematic value of these is problematic as a rule. Diapulis (1933) mentions four such varieties: *C. azarolus* L. var. *chrysoclada* (Gdgr.) Diap. from Crete, var. *rotundiloba* Diap. from Israel, var. *hastata* Diap. from the Lebanon and var. *kurdistanica* Diap. from Iraq. One variety, *C. azarolus* L. var. *microphylla* Bornm. has been described by Bornmüller (1911) from Iran. Two further varieties I have described for the region of Turkey (Browicz 1972b) namely *C. aronia* (L.) Bosc var. *dentata* Browicz (Fig. 4) and var. *minuta* Browicz (Fig. 5). The latter one is possibly identical with var. *microphylla* of Bornmüller, however I do not know its type herbarium specimen, and Bornmüller's diagnosis gives only the size of the leaves, not mentioning the size of flowers and inflorescences. As regards the relation between *C. aronia* and other hawthorns of south west Asia, the species is closely akin to *C. sinaica* Boiss., which however has glabrous leaves on both surfaces, less pubescence on young shoots, a glabrous calyx and 1 - 2 stones per fruit. On the other hand it is also related to *C. orientalis* Pall., which has 5 stones per fruit, and with which it probably gives hybrids. An intermediate link between these species is the hawthorn *C. szovitsii* Pojark. with 2 - 4 stones.

KAZIMIERZ BROWICZ

Crataegus aronia (L.) Bosc ex DC.

Streszczenie

Autor omawia szczegółowo zasięg *Crataegus aronia*, jednego z bardziej charakterystycznych gatunków w południowo-zachodniej Azji. O ile jego odróżnianie od innych, blisko spokrewnionych gatunków z tego terenu nie sprawia zasadniczo większych trudności, to sprawa jego właściwej nazwy jest wciąż kontrowersyjna.

Zarówno w zbiorach zielnikowych, jak i w literaturze florystycznej w równym niemal stopniu stosuje się dla niego jeszcze inną nazwę, a mianowicie *C. azarolus* L. Jedni autorzy uważają, że są to dwa, samodzielne gatunki, podczas gdy inni traktują je jako synonimy i najczęściej nazwę *C. azarolus* jako starszą stawiają na pierwszym miejscu. Sprawę tę wyjaśniła dokładnie Pojarkova (1939), według której *C. azarolus* L. występuje tylko w południowej Francji oraz we Włoszech i charakteryzuje się owocami o barwie ceglastej lub czerwonej przeważnie z dwoma pestkami, podczas gdy *C. aronia* rośnie w południowo-zachodniej Azji i ma owoce żółte z 2-3 pestkami. Żółto- i wielkoowocowe głogi wydzieliła Pojarkova w oddzielną serię *Ponticae*, do której obok *C. aronia* należą jeszcze: *C. linnaeana* Pojark. z Sycylii i południowych oraz środkowych Włoch, *C. triloba* Poir. z gór północno-zachodniej Afryki i *C. pontica* C. Koch z Zakaukazia, północnego Iranu oraz środkowej Azji, a także z kilku stanowisk w Turcji.

Zasięg *C. aronia* opracował autor na podstawie bogatych zbiorów zielnikowych, jak również danych z literatury, przyjmując (lecz z dużą dozą ostrożności), że informacje o *C. azarolus* L. z południowo-zachodniej Azji dotyczą w istocie rzeczy *C. aronia*. Głog ten rośnie na Krecie, na wyspie Rodos i na Cyprze, w południowej i częściowo środkowej Turcji, w zachodniej Syrii, w Libanie, w Izraelu, w zachodniej Jordanii, w północnym Iraku oraz w południowo-zachodnim Iranie. Występuje przede wszystkim na wapiennym, skalistym podłożu, w widnych lasach i w zaroślach dębowych, rzadziej w lasach sosnowych, najczęściej w średnich położeniach górskich, między 600 - 1600 m n.p.m. Jego najniższe stanowiska położone są nawet poniżej 100 m n.p.m., a najwyższe (w górzach Zagros w Iranie) sięgają po 2200 m. *C. aronia* jest bardzo wytrzymała na suszę, to też niejednokrotnie wkracza w rejony o charakterze pustynnym. Tu i ówdzie spotyka się go przy drogach lub też wśród pól uprawnych, gdzie być może został posadzony (jadalne owoce). W celach konsumpcyjnych jeszcze do dziś uprawiany jest w Iraku, w Libanie i w Syrii.

КАЗИМЕЖ БРОВИЧ

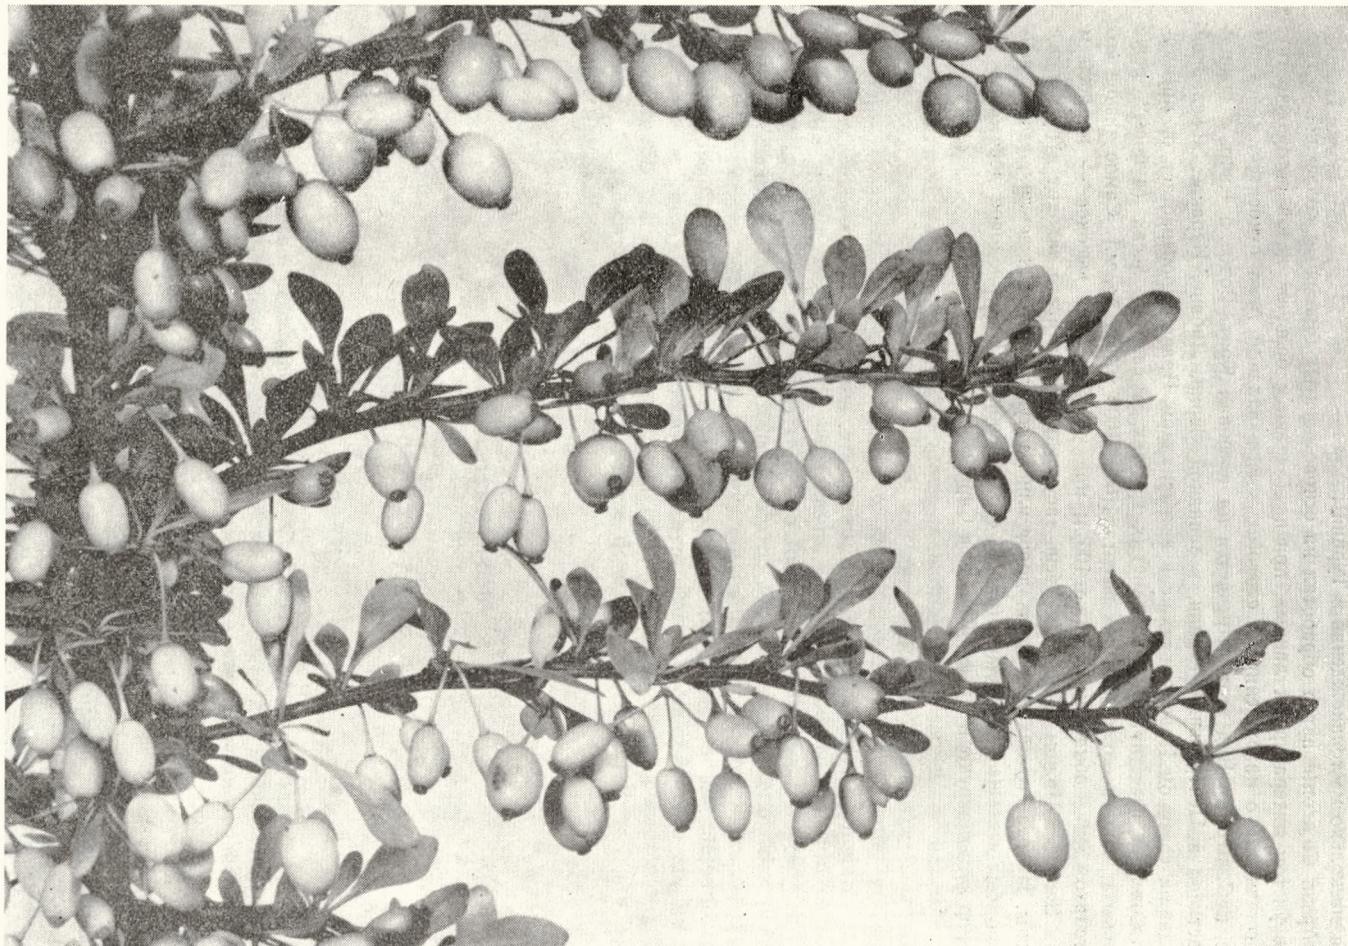

Crataegus aronia (L.) Bosc ex DC.

Резюме

Автор детально рассматривает ареал *Crataegus aronia* — одного из наиболее характерных боярышников юго-западной Азии. Выделение его из числа других близкородственных видов этого района не представляет значительных трудностей. В то же время вопрос об его правильном наименовании довольно противоречив. Как в гербарных коллекциях, так и во флористической литературе почти столь же часто к нему применяется другое название, а именно *C. azarolus* L. Одни авторы принимают их за два отдельных вида, другие считают эти названия синонимами и чаще всего ставят название *C. azarolus* на первое место как приоритетное. Обстоятельно разобралась в этом вопросе Пояркова (1939), установившая, что *C. azarolus* L. встречается только в Южной Франции и в Италии и характеризуется плодами кирпичного или красного цвета, преимущественно с двумя косточками. Второй вид — *C. aronia* произрастает в юго-западной Азии и имеет жёлтые плоды с двумя-тремя косточками. Боярышники с крупными жёлтыми плодами Пояркова выделила в особую серию *Ponticae*, к которой принадлежат, кроме *C. aronia*, также *C. linnaeana* Pojark. (Сицилия, южная и центральная Италия), *C. triloba* Poir. (горы се-

веро-западной Африки), *C. pontica* C. Koch (Закавказье, северный Иран, Средняя Азия, несколько местонахождений в Турции).

Ареал *C. aronia* автор обработал на основе богатых гербарных коллекций, а также с учётом литературных данных, приняв (однако с большой дозой осторожности), что сообщения о нахождении *C. azarolus* в юго-западной Азии относятся, на самом деле, к *C. aronia*. Вид этот встречается на островах Крит, Родос и Кипр, в южной и частично в Центральной Турции, в западной Сирии, Либане, Израиле, в западной Иордании, северном Ираке, а также в юго-западном Иране. Произрастает он преимущественно на известняковых каменистых грунтах, в светлых лесах (дубовых, реже сосновых), чаще всего на средних высотах (600 - 1600 м над ур. м.). Самое низкое его местонахождение обнаружено ниже 100 м над ур. м., самое высокое — на 2000 м (горы Загрос в Иране). *C. aronia* очень засухоустойчив и часто заходит в пустынные районы. Иногда его находят вдоль дорог или на культивируемых землях, где он возможно был высажен человеком (плоды его съедобны). Как плодовое дерево его до сих пор культивируют в Иране, Либане и Сирии.
